HORT/AGRON 603
ANOVA Review Problems 3
Write out the analysis of variance (source of variation and df) for each of the problems below and show F tests with arrows for the fixed model, unless otherwise instructed.

1. Experiment with 3 varieties of asters to compare 4 levels of growth hormone to induce branching. Installed as a randomized complete block design with 3 replications.
2. Example 1 with 5 samples per plot.
3. An experiment is performed to evaluate the growth and yield of upland taro at 3 ages of harvest, 3 planting densities, and 2 levels of nitrogen. 3 replicates will be installed.
a. Sketch one replicate of the experiment installed ina randomized complete block design, and show the treatments clearly. Write out ANOVA and show F tests on fixed and random models.
b. Sketch one replicate of the experiment installed in a split plot design with age of harvest as the whole plot and the other treatment combinations as the subplots. Write out ANOVA and do F tests on fixed and random models (all variables either fixed or random).
c. Sketch one replicate of the experiment installed in a split-split plot design with age of harvest as the whole plot, planting density as the subplot, and nitrogen as the subsubplot. Write out ANOVA and do F tests on the fixed model.
4. Four different ripening agents (RA) are applied to bunches of bananas in two concentrations; two bunches of bananas are sprayed with concentration C1 of each RA, and 4 bunches of bananas are sprayed with concentration C2 of each RA (days to ripening are the data analyzed). Show F tests for the appropriate model.
5. Example 4 with 5 bananas (fingers) taken from each bunch for brix (sugar) determination. Show F tests for the appropriate model.
6. A split block design is installed with 4 replicates, 3 Zn levels and 4 P levels. The experiment is planted at 3 locations.
7. Four treatments applied to papayas, in RCB with 4 reps. Data were collected from 4 successive harvests.
8. Experiment in a split-split plot design with 4 A treatments, 3 B treatments, 2 C treatments, and 3 reps. $(\mathrm{A}=\mathrm{MP}, \mathrm{B}=\mathrm{SP}, \mathrm{C}=\mathrm{SSP})$.
9. A balanced lattice with 49 entries
10. Cattle are grown on 3 different pastures; 10 cattle on pasture 1,7 on pasture 2,13 on pasture 3. Data are taken on the weight of T-bone steaks, two from each animal.
11. A series of nitrogen experiments with 0,50 , and $100 \mathrm{~kg} \mathrm{~N} / \mathrm{ha}$ were instaled on flooded rice in 7 locations as a RCB with 3 replicates at each location. Write out ANOVA and show F tests for the fixed and random models (both locations and N fixed or random).
12. Have 4 pens in a barn and want to compare 4 sources of carbohydrate in the feed of cattle. Have 9 animals in each pen and each pen is given one of the sources of carbohydrate. Data are gain in weight of the animals.
13. Have 9 pens and want to compare 3 sources of protein in the diet of hogs (pigs). Have 5 hogs per pen and each set of 3 pens is given one of the sources of protein so have 3 replicates. Data are rate of gain of the animals.
14. Have 25 cows, there are 5 cows each of 5 different ages. Five rations are to be compared so a different ration is fed to each cow in each age group. Cows are kept in 5 pens (one cow of each age group in each pen) and each pen is fed one of the rations. Data are amount of milk produced during the test period.
15. An experiment is conducted to measure the changes in the level of iron ( Fe ) in blood over a six-week period as affected by feeding 4 rates of an iron supplement to 5 animals in each treatment. Blood samples are collected weekly.
16. An experiment is installed on a hillside on which a gradient of sand exists across the hillside. Therefore, there are gradients in two directions, the slope of the hill and the sand gradient at approximately right angles to it. The experiment compares yield response of soybeans to 2 levels of P and 3 levels of Zn . Use the appropriate number of replicates.
17. Three plants were sampled randomly from each plot of a RCB experiment consisting of 3 reps of 5 treatments at 3 locations.
18. Two plants were sampled randomly every month for 4 months from each plot of a RCB experiment consisting of 2 reps of 5 treatments.
19. Sweetness (brix) was determined on 4 mangos per tree from 3 trees of each of 5 varieties.
20. 6 species of trees were compared in a latin square design.
21. 5 varieties of gardenia are grown at 3 temperatures in growth chambers to evaluate temperature effects on flower initiation. 4 levels of P are also compared with 3 replications in each chamber.
