Overview Database Design

• Conceptual Design
  – Use entity-relationship (aka ER) model represented pictorially as ER diagrams
  – Map ER model to relational schema

• Questions to ask yourself
  – What are the entities and relationships in the application?
  – What information about these entities and relationships should we store in the database?
  – What are the integrity constraints or business rules that hold?
ER Model Basics: Entities

- **Entity**: Real-world object distinguishable from other objects. An entity is described (in DB) using a set of *attributes*.
- **Entity Set**: A collection of similar entities. E.g., all employees.
  - All entities in an entity set have the same set of attributes. (Until we consider ISA hierarchies, anyway!)
  - Each entity set has a *key*.
  - Each attribute has a *domain*.
ER Model Basics: Relationships

- **Relationship**: Association among two or more entities.

- **Relationship Set**: Collection of similar relationships.
  - An n-ary relationship set $R$ relates $n$ entity sets $E_1 \ldots E_n$; each relationship in $R$ involves entities $e_1 \ E_1, \ldots, e_n \ E_n$
  - Same entity set could participate in different relationship sets, or in different “roles” in same set.
Cardinality Ratios of Relationships

- Consider binary relationships, i.e., between two entity sets
- Alternate notation: 1:1, 1:M, M:1, M:N

![Diagram showing 1-to-1, 1-to-Many, Many-to-1, Many-to-Many relationships]
Key Constraints

- Consider Works_In: An employee can work in many depts; a dept can have many employees: m-to-m
- Consider Manages: each dept has at most one manager
- Dept has a **key constraint** on Manages: each instance of dept appears in at most one instance of manages
- Denoted by an arrow: given a dept entity we can uniquely identify the manages relationship in which it appears
Participation constraints

- Does every dept have a manager?
- If so, this is a **participation constraint**: the participation of dept in Manages is said to be *total* (vs. *partial*). Denoted by thick/double line
- Meaning that every Dept entity must appear in an instance of the Manages relationship
Set Theoretic Formulation

- **Partial Participation**: Not all members of the Employees entity set take part in the manages relations.
- **Total Participation**: All members of the Dept entity set take part in the manages relationship.
- Dept has a **key constraint** on Manages: each member of the dept entity set takes part in at most one member of the manages relationship set.
Weak Entities

- A **weak entity** can be identified uniquely only by considering the primary key of another (owner) entity.
- Owner entity set and weak entity set must participate in a one-to-many relationship set (one owner, many weak entities).
- Weak entity set must have total participation in this *identifying* relationship set.
- Denoted by a box with double or thick lines

![Diagram showing weak entities]

- **Employees**
  - ssn
  - name
  - lot

- **Policy**
  - cost
  - pname
  - age

- **Dependents**
  - Policy
  - Dependents
Design Choices

- Should a concept be modeled as an entity or an attribute?
- Should a concept be modeled as an entity or a relationship?
- Identifying relationships: Binary or ternary? Aggregation?
- How much semantics to capture in the form of constraints?
Entity vs. Attribute

- Depends upon how we want to use the address information, and the semantics of the data:
  - If we have several addresses per employee, *address* must be an entity (since attributes cannot be set-valued).
  - If the structure (city, street, etc.) is important, e.g., we want to retrieve employees in a given city, *address* must be modeled as an entity (since attribute values are atomic).
Logical DB Design: ER to Relational

• Entity sets to tables:

CREATE TABLE Employees
(ssn CHAR(11),
name CHAR(20),
lot INTEGER,
PRIMARY KEY (ssn))
Relationship Sets to Tables

- Attributes of the relation must include:
  - Keys for each participating entity set (as foreign keys).
    - This set of attributes forms a **superkey** for the relation.
  - All descriptive attributes.

```sql
CREATE TABLE Works_In(
  ssn CHAR(11),
  did INTEGER,
  since DATE,
  PRIMARY KEY (ssn, did),
  FOREIGN KEY (ssn) REFERENCES Employees,
  FOREIGN KEY (did) REFERENCES Departments
)
```
Translating ER Diagrams with Key Constraints

- Map relationship to a table:
  - Note that did is the key now!
- Since each department has a unique manager, we could instead combine Manages and Departments.

```sql
CREATE TABLE Manages(  
  ssn CHAR(11), did INTEGER, since DATE,  
  PRIMARY KEY (did),  
  FOREIGN KEY (ssn) REFERENCES Employees,  
  FOREIGN KEY (did) REFERENCES Departments)
```

```sql
CREATE TABLE Dept_Mgr(  
  did INTEGER,  
  dname CHAR(20),  
  budget REAL,  
  ssn CHAR(11), since DATE,  
  PRIMARY KEY (did),  
  FOREIGN KEY (ssn) REFERENCES Employees)
```
Participation Constraints in SQL

- We can capture participation constraints involving one entity set in a binary relationship, but little else (without resorting to \texttt{CHECK} constraints).

```sql
CREATE TABLE Dept_Mgr(
  did INTEGER,
  dname CHAR(20),
  budget REAL,
  ssn CHAR(11) NOT NULL,
  since DATE,
  PRIMARY KEY (did),
  FOREIGN KEY (ssn) REFERENCES Employees,
  ON DELETE NO ACTION)
```
Translating Weak Entity Sets

- Weak entity set and identifying relationship set are translated into a single table.
  - When the owner entity is deleted, all owned weak entities must also be deleted.

```sql
CREATE TABLE Dep_Policy (  
  pname CHAR(20),  
  age INTEGER,  
  cost REAL,  
  ssn CHAR(11) NOT NULL,  
  PRIMARY KEY (pname, ssn),  
  FOREIGN KEY (ssn) REFERENCES Employees,  
  ON DELETE CASCADE)
```
ISA Hierarchies

- As in C++, or other PLs, attributes are inherited.
- If we declare A ISA B, every A entity is also considered to be a B entity.

- **Overlap constraints**: Can Joe be an Hourly_Emps as well as a Contract_Emps entity? *(Allowed/disallowed)*
- **Covering constraints**: Does every Employees entity also have to be an Hourly_Emps or a Contract_Emps entity? *(Yes/no)*
Translating ISA Hierarchies to Relations

**General approach:**
- 3 relations: Employees, Hourly_Emps and Contract_Emps.
  - *Hourly_Emps:* Every employee is recorded in Employees. For hourly emps, extra info recorded in Hourly_Emps (*hourly_wages, hours_worked, ssn*); must delete Hourly_Emps tuple if referenced Employees tuple is deleted).
  - Queries involving all employees easy, those involving just Hourly_Emps require a join to get some attributes.

**Alternative:** Just Hourly_Emps and Contract_Emps.
  - *Hourly_Emps:* *ssn, name, lot, hourly_wages, hours_worked.*
  - Each employee must be in one of these two subclasses.
Unified Modeling Language

- Standardized general-purpose modeling language for software design
- Based on object-oriented model
- Class diagrams

<table>
<thead>
<tr>
<th>UML</th>
<th>E/R Model</th>

UML Classes

ER Entity Set

UML Class

Movies

- title
- year
- length
- genre

Class name

Methods section typically not used in data modeling
Associations

Cardinality constraints: one instance of Stars can be connected to at least 0 instance of movies and at most infinite instances of movies.
Referential Integrity

Aggregation: Must be 0..1 (includes 1..1)

Composition: Must be 1..1
Every president runs exactly one studio

Aggregation never named
Association Classes

```
Sub-Class Hierarchies
Modeling Tips

• Faithful to the semantics of the application
• Model only what is needed in the application
• Minimize redundancy (why?)
• Simple is good
• If the model is getting too complicated, take a step back and ask
  – Am I conceptualizing the right entities?
  – Am I thinking of the right relationships?
  – Should some relationships become entities? Vice versa?
  – Should some attributes become entities? Vice versa?
