ICS 321 Data Storage & Retrieval

Transaction Processing (ii)

Asst. Prof. Lipyeow Lim
Information & Computer Science Department
University of Hawaii at Manoa
Lock-based Concurrency Control

- **Strict Two-phase Locking (Strict 2PL) Protocol**: 
  - Each Xact must obtain a *S (shared)* lock on object before reading, and an *X (exclusive)* lock on object before writing.
  - All locks held by a transaction are released when the transaction completes
    - (Non-strict) 2PL Variant: Release locks anytime, but cannot acquire locks after releasing any lock.
    - If an Xact holds an X lock on an object, no other Xact can get a lock (S or X) on that object.

- **Strict 2PL** allows only serializable schedules.
  - Additionally, it simplifies transaction aborts
  - (Non-strict) 2PL also allows only serializable schedules, but involves more complex abort processing
Example (Strict 2PL)

- Consider the dirty read schedule

<table>
<thead>
<tr>
<th>T1</th>
<th>T2</th>
<th>T1</th>
<th>T2</th>
</tr>
</thead>
<tbody>
<tr>
<td>A=A+100</td>
<td>A=1.06*A</td>
<td>X(A)</td>
<td>X(A)</td>
</tr>
<tr>
<td>B=B-100</td>
<td>Commit</td>
<td>R(A)</td>
<td>R(A)</td>
</tr>
<tr>
<td>Abort</td>
<td></td>
<td>W(A)</td>
<td>W(A)</td>
</tr>
</tbody>
</table>

With Strict 2PL, T2 can only access A when T1 aborts

A = 20
A = 120
Dirty read on A!
A = 127.2

A = 20
A = 120

X(A)
R(A)
W(A)
X(B)
R(B)
W(B)
Abort

X(A)
R(A)
W(A)
Commit
Example (Non-Strict 2PL)

- Consider the dirty read schedule

<table>
<thead>
<tr>
<th>T1</th>
<th>T2</th>
</tr>
</thead>
<tbody>
<tr>
<td>A = A + 100</td>
<td></td>
</tr>
<tr>
<td>B = B - 100</td>
<td></td>
</tr>
<tr>
<td>Abort</td>
<td></td>
</tr>
</tbody>
</table>

A = 20
A = 120
A = 127.2

With non-strict 2PL, T2 can still read uncommitted data if T1 aborts!
Deadlocks

• Cycle of transactions waiting for locks to be released

• DBMS has to either prevent or resolve deadlocks

• Common approach:
  – Detect via timeout
  – Resolve by aborting transactions
Aborting a Transaction

• If a transaction $T1$ is aborted, all its actions have to be undone.
  – Not only that, if $T2$ reads an object last written by $T1$, $T2$ must be aborted as well!

• Most systems avoid such cascading aborts by releasing a transaction’s locks only at commit time.
  – If $T1$ writes an object, $T2$ can read this only after $T1$ commits.

• In order to undo the actions of an aborted transaction, the DBMS maintains a log in which every write is recorded.
  – This mechanism is also used to recover from system crashes: all active Xacts at the time of the crash are aborted when the system comes back up
Lock Granularity

• What should the DBMS lock?
  – Row?
  – Page?
  – A Table?

```
UPDATE Sailors
SET rating=0
WHERE rating>9

SELECT * FROM Sailors

SELECT * FROM Sailors
WHERE rating < 2

UPDATE Boats
SET color='red'
WHERE bid=13

UPDATE Boats
SET color='blue'
WHERE bid=100
```
Crash Recovery

• **Transaction Manager**: DBMS component that controls execution (eg. managing locks).

• **Recovery Manager**: DBMS component for ensuring
  
  – **Atomicity**: undo actions of transactions that do not commit
  
  – **Durability**: committed transactions survive system crashed and media failures

• Assume atomic writes to disk.
The Log

• The following actions are recorded in the log:
  – *Ti writes an object*: the old value and the new value.
    • Log record must go to disk *before* the changed page! (Write Ahead Log property)
  – *Ti commits/aborts*: a log record indicating this action.

• Log records are chained together by Xact id, so it’s easy to undo a specific Xact.

• Log is often *duplexed and archived* on stable storage.

• All log related activities (and in fact, all CC related activities such as lock/unlock, dealing with deadlocks etc.) are handled transparently by the DBMS.
Recovering from a Crash

• There are 3 phases in the Aries recovery algorithm:
  
  – **Analysis**: Scan the log forward (from the most recent checkpoint) to identify all Xacts that were active, and all dirty pages in the buffer pool at the time of the crash.
  
  – **Redo**: Redoes all updates to dirty pages in the buffer pool, as needed, to ensure that all logged updates are in fact carried out and written to disk.
  
  – **Undo**: The writes of all Xacts that were active at the crash are undone (by restoring the *before value* of the update, which is in the log record for the update), working backwards in the log. (Some care must be taken to handle the case of a crash occurring during the recovery process!)
